## Electoral Accountability and Corruption: Evidence from the Audits of Local Governments

By CLAUDIO FERRAZ AND FREDERICO FINAN\*

*We show that political institutions affect corruption levels. We use audit reports in Brazil to construct new measures of political corruption in local governments and test whether electoral accountability affects the corruption practices of incumbent politicians. We find significantly less corruption in municipalities where mayors can get reelected. Mayors with reelection incentives misappropriate 27 percent fewer resources than mayors without reelection incentives. These effects are more pronounced among municipalities with less access to information and where the likelihood of judicial punishment is lower. Overall our findings suggest that electoral rules that enhance political accountability play a crucial role in constraining politician's corrupt behavior. (JEL D72, K42, O17)*

The abuse of entrusted power by politicians through rent-seeking and corruption is a threat to many modern democracies. Developing countries, in particular, provide seemingly endless examples of political elites diverting funds intended for basic public services such as health, schools, and roads for private gains.<sup>1</sup> While the pervasive effects of corruption on economic development have been well documented, the root causes are poorly understood.<sup>2</sup>

Variation in electoral systems is believed to explain a significant portion of the differences in corruption practices across countries. Because voters can oust corrupt politicians from office, electoral rules that enhance political accountability should constrain the behavior of corrupt politicians.<sup>3</sup> While there are convincing theoretical arguments for why political institutions affect corruption (see, for example, Roger B. Myerson 1993; Torsten Persson, Gerard Roland, and Guido Tabellini 1997), the

<sup>2</sup>See Stephen Knack and Philip Keefer (1995), Paolo Mauro (1995), and Marianne Bertrand et al. (2007) for studies examining the impacts of corruption.

<sup>3</sup>Despite a general perception that political corruption is harmful, some voters may still be willing to vote for corrupt politicians in exchange for particularistic goods or based on ideological or ethnic preferences.

empirical evidence identifying the specific electoral structures that discipline politicians' behavior suffers from at least two important shortcomings. First, most of these studies are based on indices that measure perceptions rather than actual political corruption. Second, many have relied primarily on cross-country analysis, where the inability to account for the full set of institutional arrangements that determine corruption has made results difficult to interpret (Alicia Adsera, Carles Boix, and Mark Payne 2003; Jana Kunicová and Susan Rose-Ackerman 2005; Daniel Lederman, Norman V. Loayza, and Rodrigo R. Soares 2005; Persson, Tabellini, and Francesco Trebbi 2003).

In this paper, we examine the effects of electoral accountability on corruption in local governments in Brazil. We construct new and objective measures of corruption using reports from an anticorruption program that audits municipalities for their use of federal funds. From these reports we estimate the share of total federal resources transferred to municipalities that is associated with fraud in the public procurement of goods and services, diversion of funds, and overinvoicing of goods and services.<sup>4</sup> Based on our estimates, corruption in local governments is responsible for losses of approximately US\$550 million per year. Thus, corruption at the local level, as in many other countries, has become an overarching concern (Rose-Ackerman 1999).

With estimates for corruption at the municipal level, we compare mayors serving in a first term to mayors in their second term (who face a term limit) to identify the effects of reelection incentives. Our identification uses variation only from municipalities audited at the same time and in the same state, while controlling for a full set of mayor and municipal characteristics. Also, by estimating the effects of reelection incentives on political corruption at a subnational level, we keep constant the macro-level institutions, both formal and informal, whose differences plague most cross-country analyses.

We find that mayors with reelection incentives are significantly less corrupt than mayors without reelection incentives. In municipalities where mayors are in their first term, the share of stolen resources is, on average, 27 percent lower than in municipalities with second-term mayors. The results are robust to various specifications and estimation strategies, as well as to alternative measures of corruption. Considering that municipalities receive, on average, \$2 million of federal transfers, lame-duck mayors steal approximately US\$55,000 more than first-term mayors. Assuming that in the absence of reelection incentives first-term mayors would behave as second-term mayors, reelection incentives reduce corruption by US\$160 million throughout Brazil. This is almost half of what the federal government spent in 2002 on the Bolsa Escola conditional cash transfer program—its largest social program providing stipends to over 4.8 million families all throughout Brazil. We also find that the effects of reelection incentives vary considerably according to differences in the local institutional settings that govern either the provision of information or the potential punishment corrupt politicians might suffer. For instance, among municipalities with the presence of local media or local

<sup>4</sup> Although Ferraz and Finan (2008) use the same audit reports, both the data and the sample differ in two important ways. First, here we only use municipalities that were audited prior to the 2004 municipal elections. Second, the measures constructed for this analysis are more comprehensive and extensive.

public prosecutors, we find little differential effect between first- and second-term mayors. Conversely, for the municipalities without local media, reelection incentives reduce political corruption by 9 percentage points. The effects of reelection incentives are also more pronounced in municipalities where the elections were competitive, suggesting that first-term mayors with an electoral advantage can afford to be more corrupt.

While our results are consistent with a model of electoral accountability, these findings also have alternative interpretations. First, our results may simply reflect differences in unobserved characteristics of the municipality that determine both reelection and corruption. To address this concern, we demonstrate that our results are robust to a regression discontinuity approach that compares municipalities where incumbent mayors barely won reelection in 2000 (and thus served as a second-term mayor from 2001 to 2004) to municipalities where the incumbent barely lost the election and thus was replaced by a new mayor (who then served as a first-term mayor from 2001 to 2004). Second, an obvious difference between first- and second-term mayors is that second-term mayors have been reelected. If elections serve to select the most able politicians, and ability and corruption are positively correlated, then our results overestimate the effects of reelection incentives. To test for this possibility, we compare second-term mayors with the set of first-term mayors who are reelected in the subsequent election, and are thus potentially as politically able as second-term mayors. Even under this comparison, our results remain unchanged. Finally, our results are also consistent with a simple model in which politicians learn to be corrupt over time. Although we cannot necessarily reject this hypothesis given the data, we do provide evidence that these differences in corruption levels cannot be entirely explained by learning. First, our results are robust when comparing second-term mayors with first-term mayors who have the same amount of political experience. Moreover, the fact that we observe important differences depending on the presence of media or the level of political competition is difficult to reconcile with a model of pure learning.

In addition to these robustness tests, we present two specification checks of the theory. First, we construct a measure of violations that includes less visible forms of corruption and mismanagement. Since voters are less aware of these violations, reelection incentives should not affect as directly this form of bad governance. We find that our data support this hypothesis. Second, mayors who face the possibility of reelection should refrain from rent extraction, but may also try to procure additional funds through matching grants. We find that mayors with reelection incentives are much more likely to attract federal funding for public works than second-term mayors, and this difference increases as the elections approach.

Our findings lend empirical support for the political agency models of Robert J. Barro (1973), John Ferejohn (1986), and Jeffrey S. Banks and Rangarajan K. Sundaram (1993), which highlight the importance of elections as a disciplining device.<sup>5</sup> In this respect, our results are consistent with a growing empirical literature documenting how electoral accountability, and term limits in particular, influences political behavior. Besley and Anne Case (1995) show that term limits affect the

<sup>5</sup> See Persson and Tabellini (2000) and Timothy Besley (2006) for excellent reviews of political agency models.

fiscal policy of US governors, while John A. List and Daniel M. Sturm (2006) provide evidence that they even influence secondary policies, such as environmental policy. James Alt, Ethan Bueno de Mesquita, and Shanna Rose (2009) also find that term limits affect the expected quality of incumbents.<sup>6</sup> Our paper contributes to this literature. By using objective measures of corruption and by exploiting within-country variation in reelection incentives, we provide, to our knowledge, the first test of how electoral accountability affects political corruption. Our findings also complement Ferraz and Finan (2008) who show that voters punish corrupt politicians when information about corruption practices is publicized. Together, these results suggest that electoral accountability acts as a powerful mechanism to align politicians' actions with voters' preferences.

The remainder of the paper is organized as follows. Section I presents a theoretical framework that links corruption to reelection incentives. It is within this context that we interpret our empirical results. Section II provides some basic background information on corruption in Brazil, and Section III describes the data and how we construct our measures of corruption. Our empirical strategy is discussed in Section IV. The results are presented in Section V, followed by tests of alternative explanations in Section VI. Section VII concludes the paper.

## I. Theoretical Framework

In this section, we present a simple model to help interpret our empirical findings. We utilize the political agency framework of Besley (2006), whereby voters decide whether to reelect an incumbent, but are unable to observe either his type or actions. In a world of corrupt and noncorrupt politicians, a corrupt mayor who faces the possibility of reelection can exploit this information asymmetry to increase reelection chances by refraining from rent-seeking and behaving as a noncorrupt mayor. According to this standard model, mayors who face reelection incentives will on average be less corrupt than mayors who do not.<sup>7</sup>

### A. A Simple Agency Model

Consider a two-period model with two types of politicians: a noncorrupt politician  $nc$  and a corrupt politician  $c$ . Let  $\pi$  denote the proportion of noncorrupt politicians in the pool of potential candidates. In each period, the elected politician sets a state-dependent policy  $e_t(s, i)$ , where  $i \in \{c, nc\}$  is the type of politician and  $s_t \in \{0, 1\}$  is the state of the world at time  $t$ . Each state occurs with equal probability and is observed only by the incumbent politician.

<sup>6</sup>While these studies have focused on the US governors, a related literature has investigated the effects of term limits in US state legislatures. The evidence using the introduction of legislative term-limits has been more mixed, and depends on the measure of behavior that is analyzed (Karl T. Kurtz, Bruce Cain, and Richard G. Niemi 2007). Daniel Diermeier, Michael Keane, and Antonio Merlo (2005) estimate a structural model of the behavior of members of the US Congress, and simulate the effects of imposing term limits. They find that term limits substantially increase early voluntary exit from the House.

<sup>7</sup>Filipe R. Campante, Davin Chor, and Quoc-Anh Do (2009) presents an alternative model where corruption depends on politicians' stability. Politicians facing more uncertainty about reelection (a shorter horizon) will extract more rents from power.

Given the choice of policy, voters receive a payoff of  $V$  if  $e_t = s_t$  and zero otherwise. Noncorrupt politicians set policy to maximize voters' objectives, whereas corrupt politicians receive a private benefit  $r_t$  for setting  $e_t \neq s_t$ . The private benefit is randomly drawn each period from a distribution  $G(r)$  with mean  $\mu$  and finite support  $[0, R]$ . The model assumes that  $R > \delta(\mu + E)$  where  $\delta$  is a common discount factor less than one and  $E$  denotes ego-rents that politicians enjoy from holding office.

The timing of this game is as follows. A politician is elected at the beginning of each period, after which nature reveals to the incumbent the state of the world. If he is newly elected, nature also reveals his type. Corrupt incumbents then receive a random draw from the distribution  $G(r)$  of private benefits. After policy is set, voters observe their payoffs and then decide whether to reelect the incumbent or select a challenger who has been drawn at random from the pool of potential politicians. After elections are held, the corrupt politicians receive another independent draw  $r_2$  from the distribution  $G(r)$ . Period 2 actions then follow and payoffs are realized.

The perfect Bayesian Nash equilibrium of this game requires that each politician behave optimally in each period, given the decision rule of the voters. Because the game ends in period 2, absent reelection incentives, each politician sets his preferred policy. Noncorrupt incumbents will set  $e_2(s, nc) = s_2$ , and corrupt incumbents will set  $e_2(s, c) = 1 - s_2$  to receive  $r_2$ . Since voters are better off with noncorrupt incumbents in period 2, they maximize the likelihood that a noncorrupt politician is elected to the second period.

The equilibrium in period 1 is much more intriguing. While noncorrupt incumbents will still behave in accordance with voters' objectives, corrupt politicians face a trade-off. Because the probability that a politician is noncorrupt conditional on observing  $V$  is greater than the proportion of noncorrupt types in the population, that is,

$$\begin{aligned} \Pr(i = nc | V) &= \frac{\Pr(V | i = nc) \Pr(i = nc)}{\Pr(V)} \\ &= \frac{\Pr(V | i = nc) \Pr(i = nc)}{\Pr(i = nc) + \Pr(i = c) \Pr(r_1 \leq \delta(\mu + E))} \\ &= \frac{\pi}{\pi + (1 - \pi) \Pr(r_1 \leq \delta(\mu + E))} \geq \pi, \end{aligned}$$

voters will reelect the incumbent if  $V$  is provided. Thus, a corrupt politician can either extract rents  $r_1$  in period 1 and forgo reelection, or alternatively behave as a noncorrupt politician to guarantee reelection and reap the benefits of a second term.

Given this trade-off, the probability that a corrupt politician provides voters with a positive payoff in period 1 is simply  $\Pr(r_1 \leq \delta(\mu + E))$ : the probability that  $r_1$  is less than the present value of expected future benefits from holding office in period 2. Based on the distributional assumptions of  $r_1$ , this probability, which we denote  $\lambda$ , is equal to  $G(\delta(\mu + E))$ .

Besley (2006) shows that in equilibrium noncorrupt politicians always set  $e_t = s_t$ . Corrupt politicians choose  $e_2 = (1 - s_2)$  in period 2, and  $e_1 = s_1$  in period 1, provided they earn sufficiently small rents. All politicians who choose  $e_1 = s_1$  will get

reelected. In equilibrium, if the ratio of disciplined politicians to nondisciplined politicians is larger than the share of noncorrupt types, i.e.,  $\lambda/(1 - \lambda) \geq \pi$ , then rent extraction will, on average, be higher in the second period than in the first period, that is,<sup>8</sup>

$$\begin{aligned} & (1 - \pi)(1 - \lambda) \int_{r_1 \geq \delta(\mu+E)}^R rdG(r) \\ & \leq (1 - \pi)\lambda \int_0^R rdG(r) + (1 - \pi)(1 - \lambda)(1 - \pi) \int_0^R rdG(r). \end{aligned}$$

The intuition for this result is simple. When faced with the possibility of reelection, corrupt politicians have the incentive to reduce rent extraction and provide more public goods. Assuming the disciplining effect  $\lambda$  is sufficiently large, rents will on average be higher in the second period, relative to the first period. We take this main testable prediction to the data by comparing the corruption levels of first-term mayors who face the possibility of reelection to the corruption levels of second-term mayors who are no longer eligible for reelection.

While our model predicts that second term mayors will be more corrupt than first term mayors, an alternative model in which mayors learn to be more corrupt over time would also provide the same prediction, even in the absence of reelection incentives. There are, however, two additional implications that come out of a model of electoral accountability which are not present in a model based purely on learning. First, the effects of electoral accountability on corruption should depend on institutional features of the municipality that strengthen the incentives for first-term mayors to reduce corruption, such as the amount of information available to voters and the competitiveness of local elections. This is unlikely to be the case in a standard model of learning. Second, implicit in our model of reelection incentives is the assumption that voters can infer a mayor's level of corruption either by direct observation or indirectly through the lack of public goods provision. While some acts of corruption are quite visible to the public, mayors also commit other types of violations that voters care less about or are harder to detect in the absence of a formal audit. Because these types of violations may not enter into citizens' calculus when voting, we should not expect to see a difference in their levels between first- and second-term mayors. In contrast, a model of learning would predict differences in both nonvisible and visible forms of corruption. Given the richness of our data, we are able to test these additional implications of the model.

## II. Institutional Background

Brazil introduced several institutional changes that facilitate the test of whether electoral accountability affects political corruption. Figure 1 presents a timeline of these events. First, reelection incentives were introduced in 1997 through a constitutional

<sup>8</sup>The condition that  $\lambda/(1 - \lambda) \geq \pi$  is sufficient but not necessary for rents to be higher in the second period. Rents are higher in the second period if the following inequality holds:  $\pi \int_{r_1 \geq \delta(\mu+E)}^R rdG(r) < (\lambda/(1 - \lambda)) \int_{r_1 \geq \delta(\mu+E)}^R rdG(r) + (\lambda + (1 - \lambda)(1 - \pi)) \int_0^{\delta(\mu+E)} rdG(r)$ .

FIGURE 1. TIMELINE OF THE ELECTORAL CYCLES AND AUDIT TIMING

*Notes:* Figure shows the timing of Brazil's municipal elections and the introduction of the audit program. It also depicts the period over which the federal funds were audited and when the constitutional amendment allowing for a second consecutive term in office took place.

amendment that enabled mayors to run for a second consecutive term in 2000 elections. Second, in 2003 the *Controladoria Geral da União* (CGU) introduced an ambitious anticorruption program that audits municipalities for their use of federal funds. These audit reports provide objective measures of corruption at the municipal level for the 2001–2004 electoral term.<sup>9</sup> These data, combined with the constitutional amendment, allow us to compare the corruption levels between municipalities where mayors are in their first term to those where mayors are in their second term.

#### A. Brazilian Mayors and Their Political Horizons

Brazil is one of the most decentralized countries in the world. Local governments receive, on average, \$35 billion per year from the federal government to provide a significant share of public services in the areas of education, health, transportation, and local infrastructure. Despite some constitutional mandates that allocate portions of the budget to certain sectors, the mayor in conjunction with local legislators decide how to spend these resources. Each year the mayor proposes a detailed budget, itemizing spending on all programs and public work projects. The local legislature analyzes the budget proposal and then returns it to the mayor with or without line-items vetoes. Upon receiving the revised budget, the mayor then decides how much to spend on all of the approved items. With the large influx of resources to municipalities, local politicians, and particularly mayors, are important political figures both at the local and in some cases the national level.

Given these potential benefits from office, it is not surprising that over 73 percent of mayors run for reelection. But the fact that only 40 percent of mayors have been reelected since the introduction of a second consecutive term is surprising, especially compared to the large incumbency effects that exist in United States.<sup>10</sup>

<sup>9</sup>Municipal elections are held countrywide at the end of the year. The new administration begins in January of the following year.

<sup>10</sup>Other developing countries, such as India, do display small or even negative incumbency effects (Leigh L. Linden 2004).

Because reelection is not guaranteed, mayors who face the possibility of reelection have a strong incentive to perform well in office.

Although mayors can hold office for only two consecutive terms, they do have the possibility of returning after a one-term hiatus. This naturally begs the question of whether term-limits should affect a mayor's political horizon. In practice, despite the fact that second-term mayors can return to office, few actually do. Among the mayors who were in their second term during 2001–2004, only 12 percent were reelected in 2008. Moreover, only 9 percent even run for higher offices (i.e., state or national congress, senate, or governor). Thus given the low probability of returning to political office in the future, it is reasonable to expect the average second-term mayor to behave as if he is serving his last term. Even if this were not the case and term-limits do not properly capture a politician's political horizon, the finding that first-term mayors behave differently from second-term mayors would simply imply that we are underestimating the true effects of reelection incentives.

### *B. Corruption Schemes in Brazil's Municipalities*

Fraud in the procurement of goods and services, diversion of funds, and overinvoicing of goods and services are among the most common ways local politicians find to appropriate resources. Other common irregularities include incomplete public works (paid for but unfinished) and the use of fake receipts and phantom firms (i.e., firms that only exist on paper).

Some examples are useful to illustrate these corruption technologies. A common scheme used to divert public resources in the municipalities of El Dorado dos Carajés and Porto Seguro, for example, includes the creation of phantom firms, simulation of the call for bids, and kickbacks to government officials.<sup>11</sup> In other contracts, although existing firms did win the bids, none of them was even aware that they had participated in the bidding process. The local administration used the names of these firms in fake receipts to appropriate resources for public goods that were never provided.

Another irregular practice, common in several municipalities, is a noncompetitive procurement process. While Brazilian law requires at least three firms to participate in any call for bids involving projects in excess of \$30,000 per year, the municipality of Itapetinga in the state of Bahia, for example, highlights one of the many ways local politicians have manipulated the process. In 2002 and 2003, the federal government transferred to Itapetinga \$110,000 for the purchase of school lunches. In 12 out of the 16 calls for bids, only one bid was ever supplied. It was later discovered that each call for bids was posted only one hour prior to its deadline, and, not surprisingly, only a firm owned by the mayor's brother posted within the time limit. This same scheme was uncovered for other social programs in the areas of education and health.

Mayors also divert funds, intended for education and health projects, toward the purchase of cars, fuel, apartments, or payment of their friends' salaries. In some cases, the mayor himself is a direct beneficiary. For example, in Paranhos, Mato Grosso do Sul, \$69,838 was paid to implement a rural electrification project. As it turns out, one of the farms benefitting from the project was owned by the mayor.

<sup>11</sup> These descriptions are based on several CGU reports and press releases available at [www.presidencia.gov.br/cgu](http://www.presidencia.gov.br/cgu).

### C. Brazil's Anticorruption Audit Program

In May 2003 the government of Luiz Inácio Lula da Silva started an unprecedented anticorruption program based on the random auditing of municipal government expenditures. The program, which is implemented through the CGU, aims to discourage misuse of public funds among public administrators and to foster civil society participation in the control of public expenditures.

The program started with the audit of 26 randomly selected municipalities, one in each state of Brazil. It has since expanded to auditing 50 and later 60 municipalities per lottery, from a sample of all Brazilian municipalities with fewer than 450,000 inhabitants.<sup>12</sup> The lotteries, which are held on a monthly basis at the Caixa Econômica Federal in Brasília, are drawn in conjunction with the national lotteries. To assure a fair and transparent process, representatives of the press, political parties, and members of the civil society are invited to witness the lottery.

Once a municipality is chosen, the CGU gathers information on all federal funds transferred to the municipal government from 2001 onward. Approximately 10 to 15 CGU auditors are then sent to the municipality to examine accounts and documents, and to inspect for the existence and quality of public work construction and delivery of public services. Auditors also meet members of the local community, as well as municipal councils, in order to get direct complaints about any malfeasance.<sup>13</sup> After approximately one week of inspections, a detailed report describing all the irregularities found is submitted to the central CGU office in Brasília. The reports are then sent to the *Tribunal de Contas da União* (TCU), to public prosecutors, and to the legislative branch of the municipality. For each municipality audited, a summary of the main findings is posted on the Internet and disclosed to media sources. It is from these reports that we construct an objective measure of corruption.

## III. Data

This section describes how we constructed our measures of corruption and mismanagement. We then present summary statistics of the variables used in the analysis.

### A. Measuring Corruption from the Audit Reports

As with any illegal activity, obtaining data on corruption is a difficult task. Several empirical studies that focus on illegal behavior have used indirect evidence to analyze its determinants and consequences (see, for example, Mark Duggan and Steven D. Levitt 2002; Raymond Fisman 2001; Fisman and Shang-Jin Wei 2004; Oriana Bandiera, Andrea Prat, and Tommaso Valletti 2009). A growing body of literature, however, has tried to assess corruption more directly by focusing on two forms: bribery of public officials and the theft of public resources (Svensson 2003; Di Tella and Schargrodsky 2003; Reinikka and Svensson 2004; Olken 2007).

<sup>12</sup>This excludes approximately 8 percent of Brazil's 5,500 municipalities, comprising mostly the state capitals and coastal cities.

<sup>13</sup>These auditors are hired based on a public examination, and prior to visiting the municipality they receive extensive training on the specificities of the sampled municipality. Also, there is a supervisor for each team of auditors.

Our approach, although related to the studies cited above, uses a methodology made possible by the availability of audit reports from Brazil's anticorruption program. Each audit report contains the total amount of federal funds transferred to the municipal administration and the amount audited, as well as an itemized list describing each irregularity found by the auditors and, in most cases, the amount of funds involved. Audit reports were available in the beginning of 2004 for 496 municipalities randomly selected across the first 11 lotteries of the anticorruption program.<sup>14</sup>

Although local corruption in Brazil assumes a variety of forms, most corruption schemes in local governments are associated with three types of violations: (i) fraud in the procurement of public goods and services; (ii) diversion of public funds for private gain; and (iii) overinvoicing of goods and services. Thus, for coding purposes, we define as political corruption any irregularity associated with one of these three nonmutually exclusive categories. Specifically, we classify diversion of resources as any irregularity involving the embezzlement of public funds. This typically occurs in two situations: (i) federally transferred resources simply "disappear" from municipal bank accounts; and (ii) the municipality claimed to have purchased goods and services that were never provided, which is determined when there is no proof of purchase and community members confirm that the goods were in fact not delivered. We classify overinvoicing as any irregularity in which auditors determined that the goods and services were purchased at a value above market price. We classify the irregularity as an irregular public procurement when there is an illegal call for bids where the contract was awarded to a "friendly firm" and the public good was not provided. These firms are usually connected directly to the mayor and/or his family or do not even physically exist. Often, corruption involving illegal public procurements includes any combination of: (i) use of nonexistent firms in the bidding process; (ii) use of fake receipts to pay for goods and services; (iii) overinvoicing of prices to increase the amount paid for the goods and services. These practices are not only the most common ways by which local politicians divert public resources, but in many instances represent complementary technologies (see Antoninho Marmo Trevisan et al. 2004).<sup>15</sup>

We read each audit report and categorize the irregularities listed by the auditors into one of the several categories of corruption listed above.<sup>16</sup> Based on the coding of the reports, we define as our principal measure of corruption the total amount of resources related to corrupt activities, expressed as a share of the total amount of resources audited. While this is our preferred measure, we also report two additional indicators of corruption: the number of irregularities related to corruption and the share of service items associated with corruption, which simply divides the number of irregularities related to corruption by the number of service items audited.

<sup>14</sup>Only 26 municipalities were selected in the first lottery. From lottery 2 to lottery 9, 50 municipalities were chosen in each. Starting on the tenth lottery in May of 2004, the CGU increased the number of municipalities chosen to 60. In our estimation sample, we lose 20 municipalities because of missing values for the covariates. To including these municipalities does not affect our estimates of the unadjusted relationship between corruption and reelection incentives.

<sup>15</sup>To give a better sense of the irregularities found and the procedure used to code corruption, we present in the Appendix some specific examples from the audit reports.

<sup>16</sup>We also used two independent research assistants to code the reports in order to provide a check on our coding.

There are at least two reasons we calculate these additional measures. First, although highly correlated with our main measure, these other indicators help to distinguish whether second-term mayors also engage in more corrupt transactions. Second, in coding the amount of stolen resources, a dollar amount was not available for all listed irregularities. While coding these cases as zero underestimates the amount of corruption, this could create a bias for testing reelection incentives if the cases occurred disproportionately more for first-term mayors. By using additional measures we include these irregularities and thus avoid the potential bias.<sup>17</sup>

The corruption measures used in this analysis are different from the indicator used in Ferraz and Finan (2008), even though these data come from the same policy experiment. In Ferraz and Finan (2008), we construct a measure that captured the information that voters received based on an extensive summary of the audit reports that the CGU provided to various media sources and the municipality. The purpose of the measures used in this analysis is to have a more comprehensive and complete measure of the corruption that occurred from 2001 to 2003. Hence, we complement the information available in the audit reports posted on the Internet with more detailed audit reports provided by the CGU office.

As described above, our corruption measure captures the more blatant acts of corruption. But mayors commit other violations that are either harder to detect or that voters care less about.<sup>18</sup> To measure these types of nonvisible violations, we create an index of mismanagement where we count the number of violations and divide it by the number of service items audited.<sup>19</sup> Some examples are useful to illustrate this measure. A common violation in the procurement of public goods occurs when fewer than three firms bid for a public contract. This can occur for a variety of reasons, such as ineptitude in publicizing the call for bids, lack of suppliers in the smaller municipalities, or perhaps even corruption. But in the cases where the public good is provided, we code this violation as an act of mismanagement rather than corruption, given that voters are unlikely to detect these subtler forms of fraud. Another common form of mismanagement occurs in the misuse of resources. Some of the block grants that municipalities receive stipulate that the resources be spent on goods in particular sectors, such as education or health. In some municipalities, mayors will use resources intended for health on teacher salaries or other public goods. Again, while corruption may be involved in the misuse of these funds, these resources were not being overtly diverted for private gain. Other violations are more standard and they include acts such as medicine not being properly stored, schools serving lunches that were past their expiration dates, or the mayor's office not keeping school attendance for children participating in a federal school program.

<sup>17</sup> Approximately 89 percent of the incidences of illegal procurement practices and fund diversion have a value reported by the auditors. Because the proportion of irregularities with no value listed is 4 percentage points higher for second-term mayors (although not statistically significant), if anything, we are underestimating the effect of reelection incentives on the share of total resources associated with corruption.

<sup>18</sup> In many cases, these violations constitute what Bandiera, Prat and Valletti (2009) refer to as passive waste.

<sup>19</sup> Because of the time and cost involved in coding these reports, we construct this measure of mismanagement for municipalities only within a randomly selected subset of the lotteries. Thus, lotteries 8, 10, and 11 were randomly excluded and we have this measure for only 366 municipalities.

TABLE 1—SUMMARY STATISTICS OF CORRUPTION BY TYPE

	Type of irregularity				
	Diversion of funds	Illegal procurement	Overinvoicing	Corruption indicator	Mismanagement
<i>Proportion of municipalities with at least one irregularity</i>	0.536 (0.499)	0.576 (0.495)	0.071 (0.258)	0.786 (0.411)	0.986 (0.116)
<i>Conditional on at least one irregularity</i>					
Average number of irregularities	1.686 (1.006)	1.657 (0.945)	1.029 (0.171)	2.457 (1.554)	n/a
Average value of irregularity (R\$)	159,205.20 (324,303.8)	291,431.50 (578,272.1)	60,670.14 (166,733.8)	327,573.10 (627,514.2)	n/a
Share of audited resources	0.041 (0.072)	0.070 (0.093)	0.015 (0.036)	0.080 (0.109)	n/a
Share of audited items	0.047 (0.036)	0.045 (0.028)	0.029 (0.012)	0.067 (0.050)	1.647 (1.154)

Notes: This table reports descriptive statistics on the various measures of corruption computed from the audit reports. These statistics presented in columns 1–4 were computed for our sample of 476 municipalities. In column 5, the statistics were computed for 366 municipalities. Standard deviations are reported in parentheses.

B. Summary Statistics on Corruption and Mismanagement

Summary statistics for each one of the three corruption categories and the overall corruption indicator are displayed in Table 1. As seen in row 1, 58 percent of the municipalities have performed an illegal procurement practice, and 54 percent of the municipalities have diverted funds. Overinvoicing is found much less frequently, occurring in only 7 percent of our sample. After combining these indicators, we see that 79 percent of the municipalities have had at least one incidence of corruption and virtually every municipality has committed some act of mismanagement (99 percent). Moreover, those administrations that commit an act of corruption average around 2.46 corrupt violations, which is 6.7 percent of the service items audited. The average amount of resources diverted is R\$327,000 per violation, which represents 8 percent of the total amount audited. In the last column of Table 1, we also see that the ratio of acts of mismanagement to number of service items audited is 1.65.

To get a sense for how electoral accountability may affect these various irregularities, Table 2 compares these indicators between municipalities with mayors in their first term to those that have mayors serving in their second term. In the first set of columns, the share of audited resources found to be associated with corruption is 1.9 percentage points higher for second-term mayors (significant at the 95 percent level of confidence). Second-term mayors are also more corrupt in each one of the three individual categories of corruption (diversion of funds, illegal procurement practices, and overinvoicing), but it is the difference in illegal procurement that accounts for much of the difference in the aggregate measure. On average, the share of resources that is diverted illegally in the procurement of public works is 1.7 percentage points higher among second-term mayors than first-term mayors.

When corruption is measured as either the incidence of irregularities or the share of service items, in columns 4–9 of Table 2, we see further evidence in support of the theoretical predictions. Compared to first-term mayors, second-term mayors

TABLE 2— SUMMARY STATISTICS OF CORRUPTION BY FIRST- AND SECOND-TERM MAYORS

	Share of audited resources			Incidence of irregularities			Share of audited items		
	First term (1)	Second term (2)	Difference (3)	First term (4)	Second term (5)	Difference (6)	First term (7)	Second term (8)	Difference (9)
Diversion of funds	0.021	0.022	0.001 [0.005]	0.852	0.971	0.119 [0.103]	0.024	0.026	0.002 [0.003]
Illegal procurement	0.033	0.050	0.017 [0.007]	0.837	1.107	0.270 [0.100]	0.023	0.029	0.006 [0.003]
Overinvoicing	0.001	0.002	0.001 [0.001]	0.074	0.073	−0.001 [0.025]	0.002	0.002	0.000 [0.001]
Corruption	0.055	0.074	0.019 [0.009]	1.763	2.150	0.388 [0.157]	0.050	0.057	0.008 [0.005]

Notes: This table compares the various measures of corruption between first- and second-term mayors. These statistics were computed only for the 476 municipalities. Columns 1, 4, and 7 report the means for the 270 municipalities with a first-term mayor. Columns 2, 5, and 8 report the mean for the 206 municipalities with a second-term mayor. Columns 3, 6, and 9 report the difference in means, and robust standard errors of the difference are presented in brackets.

commit 0.12 and 0.27 more irregularities in the diversion of funds and illegal procurement practices, respectively, which represents 0.2 and 0.6 percentage point differences in the share of services items audited.

C. Municipal and Mayor Characteristics

The other data sources used in the analysis were obtained from the Brazilian Institute of Geography and Statistics (*Instituto Brasileiro de Geografia e Estatística* (IBGE)), *Tribunal Superior Eleitoral* (TSE), and *Tesouro Nacional* (National Treasury). The richness of these data allows us to control for a large number of municipal characteristics that are likely to be correlated with corruption practices and whose absence might otherwise confound our estimates.<sup>20</sup>

Table 3 compares differences in mean characteristics of municipalities with a first-term mayor to municipalities with a second-term mayor. Because of the lack of an experimental design and the need to assume selection on observable characteristics, it is important to understand if the determinants of corruption are significantly different across the municipalities. As the table demonstrates, there are few differences in observable characteristics between these municipalities. Out of 43 variables, only 5 are significantly different at a 95 percent level of confidence.<sup>21</sup> There is a significant difference between first- and second-term mayors in our measures of electoral performance for the 2000 municipal elections. The other significant differences across municipalities are the proportion of the population with at least a secondary school education and the share of the population living in urban areas, characteristics that are fairly correlated. In fact, the difference in the share of the urban population loses statistical significance in our regressions once we account for the difference in secondary school attainment.

<sup>20</sup> See Appendix B for a detailed description of data sources.  
<sup>21</sup> We report the 19 most important variables that are later used in our specifications.

TABLE 3— SUMMARY STATISTICS OF MAYORS AND MUNICIPALITIES

	First-term mayors	Second-term mayors	Difference
<i>Mayor characteristics</i>			
Male	0.95	0.96	−0.01 [0.020]

Total resources audited (R\$ million)	5.86	5.18	0.68 [0.75]

*Notes:* This table presents a comparison of the mean political, mayor, and socioeconomic characteristics of the municipalities between first- and second-term mayors. These statistics were computed only for the 476 municipalities that contained the full set of nonmissing characteristics. Column 1 reports the means for the 270 municipalities with a first-term mayor. Column 2 reports the mean for the 206 municipalities with second-term mayors. Column 3 reports the difference in means, and robust standard errors of the difference are presented in brackets.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

\*Significant at the 10 percent level.

#### IV. Empirical Strategy

Our main objective is to test whether reelection incentives affect the level of political corruption in a municipality. As the theory presented in Section I predicts, mayors who face reelection incentives should, on average, be less corrupt than those who are no longer eligible for reelection. To estimate these effects, the ideal experiment would be to randomly assign the possibility of reelection across municipalities and then measure the differences in corruption levels across these two groups of municipalities among mayors in their first term of office. Unfortunately, this experiment design does not exist and, given the cross-sectional nature of our data, we instead compare mayors in their first term, who still face reelection incentives, to second-term mayors using the following regression:

$$(1) \quad r_i = \beta I_i + \mathbf{X}_i \varphi + \mathbf{Z}_i \gamma + \varepsilon_i,$$

where  $r_i$  is the level of corruption for municipality  $i$ , and  $I_i$  indicates whether the mayor is in his first term. The vector  $\mathbf{X}_i$  is a set of municipal characteristics and the vector  $\mathbf{Z}_i$  is a set of mayor characteristics that determine the municipality's level of corruption. The term  $\varepsilon_i$  denotes unobserved (to the econometrician) municipal and mayor characteristics that determine corruption.

In estimating equation (1), we face two main empirical challenges. First, without random assignment of reelection incentives, unobserved characteristics of the municipality and the mayor that affect both reelection and local corruption (e.g., political ability and campaigning effort) will bias a simple OLS regression. Second, even if first- and second-term mayors were randomly assigned, the finding that second-term mayors are more corrupt could be due to the fact that they have more experience.

To illustrate these potential biases, consider a simple model that expresses the difference in corruption level between first- and second-term mayors in terms of potential outcomes. Let  $r_i^{DT}$  be the level of rents extracted by a politician at term  $t$  in a municipality where mayors can be reelected to a second term, i.e., a double-term regime,  $DT$ . The simple comparison between mayors in their first and second term is

$$\Delta = E[r_2^{DT} | \tau = 2] - E[r_1^{DT} | \tau = 1],$$

where  $\tau$  denotes a first- or second-term mayor. Let  $r_i^{ST}$  denote the levels of rents at term  $t$  in a municipality where there are no possibilities of reelection, i.e., a single-term regime,  $ST$ . We can rewrite this simple difference as

$$(2) \quad \begin{aligned} \Delta &= E[r_2^{DT} | \tau = 2] - E[r_1^{ST} | \tau = 1] + (E[r_1^{ST} | \tau = 1] - E[r_1^{DT} | \tau = 1]) \\ &= \beta + \underbrace{E[r_2^{DT} | \tau = 2] - E[r_1^{ST} | \tau = 2]}_{\text{experience}} + \underbrace{E[r_1^{ST} | \tau = 2] - E[r_1^{ST} | \tau = 1]}_{\text{ability}}, \end{aligned}$$

where  $E[r_1^{ST} | \tau = 1]$  is the expected level of rent extraction in the first period among first-term mayors who do not face reelection incentives, and  $\beta = E[r_1^{ST} | \tau = 1] - E[r_1^{DT} | \tau = 1]$  measures the causal effects of reelection incentives on corruption.

The first difference represents the potential bias associated with the effects of political experience on corruption. It compares the corruption level of a second-term mayor in his second term (i.e.,  $t = 2$ ) of a double-term regime to the amount of corruption the *same* mayor would have committed in the first period (i.e.,  $t = 1$ ) of a single-term regime. The second difference captures any bias associated with differences in either political ability or unobserved municipal level determinants of corruption. It measures the difference in the amount of corruption between what a second-term mayor would have committed in his first term of a single-term regime and what a first-term mayor commits in the first term of a single-term regime. If these differences are not zero, then OLS estimation of equation (1) will be biased.

#### *A. Controlling for Unobserved Characteristics of the Municipality*

To account for any unobserved municipal determinants of corruption that may differ between first- versus second-term mayors, we compare municipalities where incumbent mayors barely won reelection in 2000 (and thus served as second-term mayors from 2001 to 2004) to municipalities where the incumbent barely lost the election and thus was replaced by a new mayor (who then served as a first term between 2001 and 2004). As discussed in David S. Lee (2008), close elections provide a quasi-random assignment of municipalities with a first- versus second-term mayor. Thus, by comparing elections where the incumbents won or lost by a narrow margin, we control for many of the unobserved characteristics of the municipality that determine both reelection and corruption levels, such as the ideological preferences of voters or the quality of the pool of candidates.<sup>22</sup>

To exploit the discontinuity in the margin of victory that reelects the incumbent mayor, we modify equation (1) to estimate the following model:

$$r_i = \beta I_i + f(W_i) + X_i\varphi + Z_i\gamma + \varepsilon_i,$$

$$I_i = 1[W_i \leq 0],$$

where  $W_i$  denotes the difference in vote shares between the incumbent and the second place candidate, and  $f(W_i)$  is a smooth continuous function of margin of victory. As is typically the case in a regression discontinuity framework, there is a trade-off between precision and bias, particularly as one moves away from the discontinuity. In Section V, we present estimates that are robust to various functional form assumptions for  $f(W_i)$ .

<sup>22</sup>Ernesto Dal Bó, Pedro Dal Bó, and Jason Snyder (2009), Fernando Ferreira and Joseph Gyourko (2009), Lee, Enrico Moretti, and Matthew J. Butler (2004), and Linden (2004) also apply regression discontinuity techniques in the context of elections.

### B. *Controlling for Political Ability and Experience*

While the regression discontinuity approach does eliminate an important class of municipal-level confounds, this identification strategy does not account for any underlying differences in the unobserved characteristics of individual politicians. If, for instance, incumbent mayors are more politically able than first-term mayors, then our estimates will be overestimated, even when we restrict the sample to only those municipalities with close elections. To address differences in unobserved political ability, we instead compare second-term mayors with a subset of first-term mayors who were able to get reelected in 2004 elections. If the bias from the OLS regression comes from unobserved political ability that positively selects more able politicians into a second-term, this approach controls for a significant portion of this bias by comparing mayors who are as politically able as second-term mayors.

Another empirical challenge comes from the fact that second-term mayors are by definition more experienced than first-term mayors. Thus, if there is a learning process associated with corruption, or if it simply takes time to establish the networks that enable corrupt practices, then the difference in corruption levels between first- and second-term mayors may reflect not only reelection incentives but also political experience.<sup>23</sup>

To account for differences in experience, we collect data on all mayors who held a political position as either mayor or local legislator during the 1989–1992, 1993–1996, and 1997–2000 administrations. We can then compare the corruption of mayors facing a second-term with those serving a first-term, but who have had previous political experience. If the difference in corruption levels between first- and second-term mayors is largely due to experience, then we would expect first-term mayors who had previously been in power to have similar corruption levels to second-term mayors.<sup>24</sup>

## V. Empirical Results

This section provides evidence that municipalities where mayors face reelection incentives are associated with significantly lower levels of corruption, as measured by the share of stolen resources. These findings are robust to alternative definitions of corruption, as well as to various specifications and estimation techniques. We also explore how reelection incentives vary with local characteristics and find that the effects are stronger among municipalities where the costs of rent extraction are lower and political competition is higher. All these results are consistent with the basic predictions of a standard political agency model. We conclude this section with additional results that address several potential threats to our identification assumptions.

<sup>23</sup> As long as reducing corruption increases one's chances of getting reelected, then theoretically it is unlikely that any difference between first- and second-term mayors is strictly due to a learning-by-doing process.

<sup>24</sup> Underlying this comparison is the assumption that legislative experience is a good proxy for the additional years of experience as a second-term mayor. This is a reasonable assumption. Local legislators influence local spending and the quality of public policy in much the same way as mayors do. For instance, legislators must approve and modify the municipal budget. They are also responsible for submitting bills and petitions. While mayors and local legislators do engage in activities that require similar know-how, mayors do yield substantively more constitutional powers. But given the similarities, it is not surprising that at least 65 percent of mayors started their political career as a local legislator.

TABLE 4—THE EFFECTS OF REELECTION INCENTIVES ON CORRUPTION

Dependent variable	Share of audited resources involving corruption

State intercepts	No	No	No	No	No	Yes	Yes	Yes

Notes: This table reports the effects of reelection incentives on share of resources found to involve corruption. Columns 1–6 present the results of an OLS regression of the dependent variables listed in that column on an indicator variable for whether the mayor is in his first term. Column 7 estimates the relationship using Abadie and Imbens (2004) matching estimator, and column 8 uses a Tobit specification and reports marginal effects. The log likelihood for the Tobit estimation is 194.20. Mayor characteristics include the age, gender, education, and party affiliation. Municipal characteristics: population expressed in logarithms, percentage of the population that has at least a secondary education, percentage of the population that lives in the urban sector, new municipality, log GDP per capita per in 2002, Gini coefficient. Political and judicial institutions include: effective number of political parties in the legislature, the number of legislators divided by the number of voters, the share of the legislature that is of the same party as the mayor, and whether the municipality is judiciary district, and the amount of resources sent to the municipality expressed in logarithms. Robust standard errors are displayed in brackets.

\*\*\*Significant at the 1 percent level.  
\*\*Significant at the 5 percent level.  
\*Significant at the 10 percent level.

A. Main Results on Corruption

Table 4 presents regression results from estimating several variants to equation (1), where the dependent variable is the share of audited resources that involved corruption. Column 1 reports the unadjusted relationship between whether the mayor is in his first term and the share of stolen funds. The remaining columns correspond to specifications that include additional sets of controls. The specifications presented in columns 2–4 account for various mayors, and demographic and institutional characteristics of the municipality, whereas the specifications in columns 5 and 6 include, in addition to the other controls, indicators for when the municipality was selected for audit (lottery intercepts) and state intercepts. The specification presented in column 6, where reelection incentives are identified from only within state and lottery variation, accounts for any state-specific or lottery-specific unobservable that might have affected political corruption. It also controls for any differences across states (and in effect across time) for how the municipalities may have been audited.

From the bivariate relationship in column 1, we see that first-term mayors are associated with a 1.9 percentage point decrease in corruption. At an average corruption level of 0.074 among second-term mayors, this estimate represents a 27 percent decline. As seen in the other columns, the inclusion of additional controls has a minimal effect on the point estimate. For example, in column 6, which controls for state and lottery intercepts and various mayor and municipal characteristics,

including the amount of resources transferred to the municipality, the estimated effect is slightly larger in magnitude (point estimate =  $-0.027$ ; and robust standard error =  $0.011$ ), but statistically indistinguishable from the estimate of the unadjusted regression ( $F(1, 409) = 0.44$ ;  $p$ -value =  $0.51$ ). If we consider that on average R\$5.5 million was transferred to these municipalities, lame-duck mayors steal approximately R\$150,000 more than first-term mayors.

Columns 7 and 8 of Table 4 present the estimated effect of reelection incentives based on different functional form assumptions. In column 7, we display the estimated effects of corruption using a bias-adjusted matching estimator (Alberto Abadie and Guido W. Imbens 2006). Although the identification assumptions are similar to those of the regression analysis, the matching estimator has the advantage that it neither assumes a functional form nor extrapolates over areas of uncommon support in the observable characteristics. In addition to the matching estimator, we estimate a Tobit model to account for the left censoring of municipalities with zero share of corruption (column 8). For each alternative specification, the point estimates are consistent to the OLS estimates presented in the other columns. Using the Tobit model, the marginal effects for the entire sample increase in magnitude to  $-0.042$  (robust standard error =  $0.012$ ) compared to  $-0.027$  (robust standard error =  $0.011$ ) in the OLS regression.

Table 5 reports the effects of reelection incentives using two alternative measures of corruption. Columns 1–4 compare the number of irregularities associated with corruption between first- and second-term mayors, whereas columns 5–8 estimate the effects using the share of service items involving corruption (number of corrupt irregularities divided by the number of audited items) as the dependent variable. For each measure, we report estimates from the unadjusted relationship, our most complete model, and models that impose alternative functional forms. Under our full specification, first-term mayors are associated with 0.471 fewer acts of corruption (column 2). When compared to the average corruption among second-term mayors, this effect represents a 22 percent decline. We also find that first-term mayors are 23 percent less corrupt when measured by the share of service items found to involve corruption. This measure addresses the concern that municipalities with second-term mayors may have had more items audited. As the remaining columns demonstrate, these estimates are robust to alternative specifications and estimation procedures (i.e., matching, negative binomial, and Tobit models). Together these findings suggest that mayors who face the possibility of reelection engage in less corrupt acts than mayors who have a shorter political horizon.

### *B. Accounting for Unobserved Municipal Level Confounds*

We have shown that our estimated effects are robust to controlling for an extensive set of municipal characteristics, which are likely to proxy for many unobservable confounds. In this section, we provide even further evidence that our results are not confounded by unobserved characteristics of the municipality, such as heterogeneity across municipalities in voters' corruption preferences or the level of political patronage. Here, we identify the effects of reelection incentives using elections in which the incumbents won or lost by a narrow margin. This comparison, which provides quasi-random assignment of first-term and second-term mayors across

TABLE 5—THE EFFECTS OF REELECTION INCENTIVES ON ALTERNATIVE MEASURES OF CORRUPTION

Dependent variable	Numbers of irregularities involving corruption				Share of audited items involving corruption			
	OLS (1)	OLS (2)	Matching (3)	Negative binomial (4)	OLS (5)	OLS (6)	Matching (7)	Tobit (8)
Mayor in first term	−0.388 [0.158]**	−0.471 [0.148]***	−0.339 [0.146]**	−0.456 [0.127]**	−0.008 [0.005]	−0.011 [0.004]**	−0.010 [0.005]*	−0.009 [0.005]*

State intercepts	No	Yes	Yes	Yes	No	Yes	Yes	Yes

Notes: This table reports the effects of reelection incentives on number of irregularities associated with corruption and the share of service items involving corruption. Columns 1–2 and columns 5–6 present the results of an OLS regression of the dependent variables listed in that column on an indicator variable for whether the mayor is in his first term. Columns 3 and 7 estimate the relationship using Abadie and Imbens (2004) matching estimator; column 4 uses a negative binomial specification and column 8 uses a Tobit specification. In both columns 4 and 8, marginal effects are reported. The pseudo-likelihood for the negative binomial specification is −729.68 and the log likelihood for the Tobit is 459.40. Mayor characteristics include the age, gender, education, and party affiliation. Municipal characteristics: population expressed in logarithms, percentage of the population that has at least a secondary education, percentage of the population that lives in the urban sector, new municipality, log GDP per capita in 2002, Gini coefficient. Political and judicial institutions include: effective number of political parties in the legislature, the number of legislators divided by the number of voters, the share of the legislature that is of the same party as the mayor, whether the municipality is judiciary district, and the amount of resources sent to the municipality expressed in logarithms. Robust standard errors are displayed in brackets.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

\*Significant at the 10 percent level.

these competitive elections, eliminates an important class of potential confounds. This identification strategy does not, however, allow us to disentangle the effects of reelection incentives from a simple model of experience, or control for underlying differences in characteristics of politicians. We account for these possibilities in the next set of robustness checks.

Table 6 presents the results from the regression discontinuity design for the subset of mayors who ran for reelection. Because the sample is conditioned on the 328 incumbents who ran for reelection in 2000, column 1 presents the OLS estimates of our full specification for this subsample. The point estimate of −0.031 (robust standard error = 0.014) is both statistically and economically similar to the effects estimated for the overall sample. In columns 2–7 we present results from various RDD specifications that correspond to different functional form assumptions on the running variable—margin of victory. In columns 2–4 we estimate models where the running variable ranges from a linear specification to a cubic specification, but restrict the slopes to be constant. In columns 5–7, we relax the constant slope assumption using splines, which allows for differential slopes on either side of the discontinuity.

The RDD approach yields estimates similar to those presented in Table 4. Depending on the functional form assumptions, the coefficient on the first-term indicator varies between −0.028 and −0.047 (robust standard errors varying from 0.019 to 0.029). For instance, allowing for a cubic polynomial in the incumbent’s

TABLE 6—THE EFFECT OF REELECTION INCENTIVES ON CORRUPTION, CONTROLLING FOR UNOBSERVED MUNICIPAL CHARACTERISTICS

State intercepts	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Notes: This table reports the effects of reelection incentives on the share of resources involving corruption. The estimation samples in columns 1–7 include only municipalities where the incumbent ran for reelection. In columns 2–4, the functional form assumption for the running variable is specified at the top of each column. Mayor characteristics include the age, gender, education, and party affiliation of the mayor. Municipal characteristics: population expressed in logarithms, percentage of the population that has at least a secondary education, percentage of the population that lives in the urban sector, new municipality, log GDP per capita per in 2002, Gini coefficient. Political and judicial institutions include: effective number of political parties in the legislature, the number of legislators divided by the number of voters, the share of the legislature that is of the same party as the mayor, and whether the municipality is judiciary district, and the amount of resources sent to the municipality expressed in logarithms. Robust standard errors are displayed in brackets.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

\*Significant at the 10 percent level.

margin of victory, first-term mayors are 3.8 percentage points less corrupt than second-term mayors. The other point estimates increase in absolute magnitude as the functional form assumption is relaxed, with the exception being in column 7. With only 328 observations, the cubic spline is estimated with less precision, but the point estimate ( $= -0.028$ ) is of the same magnitude as the other estimates. In Figure 2, we depict the main results graphically using a third-degree polynomial fit. Similar to the regression results, there is approximately a 0.04 percentage point increase in corruption near the threshold, suggesting that second-term mayors are more corrupt even after controlling for the potential effects of unobserved municipal characteristics.

Our results thus far are consistent with reelection incentives reducing corrupt practices, even after accounting for both observable and unobservable differences in municipal characteristics between first- and second-term mayors. This does not preclude the possibility that individual differences between first- and second-term mayors are confounding the results. In the following sections, we explore whether differences between first- and second-term mayors in either political ability or experience can explain the observed differences in corruption levels.

C. Accounting for Political Ability

An obvious difference between first- and second-term mayors is that second-term mayors have been reelected. If elections serve to select the most able politicians,

FIGURE 2. THE EFFECTS OF REELECTION INCENTIVES ON CORRUPTION

*Notes:* Figure shows the share of audited resources involving corruption by the margin of victory for incumbents who ran for reelection in 2000. Each figure presents mean corruption for a bin size of 30 percentage points (hollow circles) along with the fitted values from a third degree polynomial fit on each side of the discontinuity. The dashed lines denote 90 percent confidence intervals. These estimates were computed for a sample size of 328 municipalities.

and ability and corruption are positively correlated, then our results overestimate the effects of reelection incentives. To explore this potential bias, we can compare the corruption levels of second-term mayors to the subset of first-term mayors who are reelected in the subsequent elections in 2004. By selecting on this subset of first-term mayors, we are comparing first- and second-term mayors with similar levels of innate political ability.

The results of this comparison are reported in column 1 of Table 7. The coefficient on the first-term indicator increases in magnitude to  $-0.040$  (robust standard error =  $0.013$ ), suggesting that second-term mayors extract a higher level of rents from office even compared to first-term mayors of similar political ability. It is important to note, however, that the larger coefficient on the first-term dummy was expected because the dissemination of the audit program decreased the probability that corrupt mayors were reelected (Ferraz and Finan 2008). To control for the effects of the audits, we use an alternative strategy where we estimate the probability of reelection using the sample of mayors who were not audited before the 2004 elections (and hence voters did not have this information) and compute the predicted probability of a first-term mayor getting reelected.<sup>25</sup> We then compare

<sup>25</sup>We constructed a propensity score for whether the mayor was reelected in the 2004 elections using various mayor and municipal characteristics. These characteristics included: the mayor's gender, education, marriage

TABLE 7—THE EFFECT OF REELECTION INCENTIVES ON CORRUPTION CONTROLLING FOR ABILITY AND EXPERIENCE

Notes: This table reports the effects of reelection incentives on the share of resources involving corruption. Column 1 compares the corruption levels of second term mayors to those of the subset of first term mayors that were reelected in the subsequent mayor elections. Column 2 compares the corruption levels of second term mayors to those of the subset of first term mayors who were predicted to be reelected, based on a propensity score. Column 3–4 is estimated on the full sample. Column 5 includes only municipalities with a second-term mayor and first-term mayors who had a mayor in a previous term. Column 6 includes only municipalities with a second-term mayor and first-term mayors who had been either a mayor or legislator in a previous term. Mayor characteristics include the age, gender, education and party affiliation of the mayor. Municipal characteristics: population expressed in logarithms, percentage of the population that has at least a secondary education, percentage of the population that lives in the urban sector, new municipality, log GDP per capita per in 2002, Gini coefficient. Political and judicial institutions include: effective number of political parties in the legislature, the number of legislators divided by the number of voters, the share of the legislature that is of the same party as the mayor, and whether the municipality is judiciary district, and the amount of resources sent to the municipality expressed in logarithms. Robust standard errors are displayed in brackets.

\*Significant at the 10 percent level.

second-term mayors to the subset of first-term mayors who were predicted to be reelected. After controlling for the effects of the audits, the point estimate reduces to −0.034 (robust standard error = 0.017) and is still significant at 90 percent confidence (see column 2).

D. Accounting for Political Experience

Even if we account for differences in ability between first- and second-term mayors, politicians in power for a longer period of time may learn to be more corrupt

status, age, and party affiliation dummies; the municipality’s log population, population with secondary school education, age of municipality, log GDP per capita, income equality, share of the legislative branch that supports the mayor, effective number of parties in 2000 election, an indicator for whether there is a judge in the municipality, and state fixed effects. The predicted indicator is equal to one if the propensity score was greater than or equal to 0.5. The estimation predicted 64 percent of the cases correctly.

over time. If this were the case, the estimated differences in corruption between first- and second-term mayors might reflect the corruption know-how accumulated over time rather than the effects of reelection incentives. In this section we provide evidence that, although second-term mayors have, on average, more political experience, additional years in office cannot fully explain the difference in corruption between first- and second-term mayors.

We start by identifying the 2001–2004 mayors who were either in power during the 1989–1992 and 1993–1996 administrations or served as local legislators during the 1997–2000 administration. If the difference in corruption levels between first- and second-term mayors is largely due to experience, then we would expect first-term mayors who had previously been in power to have similar corruption levels to second-term mayors. In column 3 of Table 7, we reestimate our full specification, but control for an indicator for whether the first-term mayor was in power in one of the three previous terms. The point estimate of  $-0.027$  (robust standard error = 0.012) is identical to the original point estimate in column 6 of Table 4. In the next column, we explore an alternative definition of political experience in which we sum the number of years that the mayor has been in office either as a mayor or legislator. As we see in column 4, controlling for previous experience flexibly increases in magnitude our point estimate to  $-0.030$  (robust standard error = 0.012).

An alternative way to account for previous experience is to compare second-term mayors with only first-term mayors who previously had been in power. Hence, we reestimate the baseline regression using all second-term mayors, but restrict first-term mayors to only those who have been mayors before (either from 1988 to 1992 or 1993 to 1996). The coefficient on first term, shown in Table 7, column 5, is  $-0.038$  (robust standard error = 0.014), further suggesting that political experience does not determine the difference in corruption levels between first- and second-term mayors.

One potential criticism to this approach is that the political networks built by a mayor during the 1992–1996 period might be lost when he spends time away from office before returning in 2001. Hence, in column 6, we reestimate the basic model comparing second-term mayors to first-term mayors with previous political experience, including experience as local legislators during the previous term. The estimated difference in corruption between first- and second-term mayors decreases slightly to the original estimate of 2.7 percentage points (robust standard error = 0.016).

#### E. Testing for Additional Implications of Reelection Incentives

*Visible versus Nonvisible Violations.*—As we discussed in Section III, our corruption measures capture fairly visible forms of corruption. Examples include such violations as the partial construction of roads and classrooms, or the construction of dams and wells on politicians' private farms. Other acts of corruption, while not directly observed, could have been easily inferred by voters, such as when teachers were forced to go on strike because the mayor had not paid their salaries in over a year, or when children are not supplied with school lunches for a school feeding program.<sup>26</sup> It is these

<sup>26</sup> See, for instance, "Desvio do FUNDEF atrasa salários de professores," *O Globo* 03/27/2005.

acts of corruption, both directly and indirectly visible, that we would expect mayors who face reelection incentives to avoid. Thus far, our results suggest this to be the case.

Mayors do, however, commit other types of violations which either voters care less about or are harder to detect in the absence of a formal audit. Because these types of violations may not enter into a voter's calculus when voting, we should not expect to see a difference in their levels between first- and second-term mayors. To test this hypothesis, we use the audit reports to classify a separate measure of mismanagement. Some incidences of mismanagement involve acts of corruption that are difficult to detect, such as when public funds are not used for their intended purposes. Others involve simple administrative violations that voters either do not care about or do not observe, such as noncompetitive bids (but where the public good is still provided). Thus, while this measure may capture some corruption, it is unlikely that voters have sufficient awareness of these violations to exact electoral retribution.

In Table 8, we present results from estimating a model similar to equation (1), where the dependent variable is the proportion of items audited involving mismanagement. Using our full specification, we find no effects of reelection incentives on acts of mismanagement. The point estimate is 0.054 (robust standard error = 0.102), which is both statistically insignificant and small in magnitude. In fact, we would have to increase the coefficient by 4 standard deviations in order to achieve an effect that is of similar magnitude to the one using the corruption index. At an average of 1.62, it implies that first-term mayors commit only 3.1 percent more acts of mismanagement than second-term mayors. In columns 2 and 3, we restrict the sample to those first-term mayors who were reelected in 2004 (column 2) or for those who were previously mayors (column 3). For both samples, we again do not find any evidence that first-term mayors commit fewer acts of mismanagement than second-term mayors. Because we coded the acts of mismanagement only for a random sample of our original data, in column 4 we reestimate the effects of reelection incentives on corruption for this new sample. As before, we find that mayors who face reelection incentives are far less corrupt than mayors who do not. The point estimate of  $-0.036$  (robust standard error = 0.013) is consistent with our previous estimates. Overall, the results presented in Table 8 are not only consistent with a model of reelection incentives but also inconsistent with a model of experience. If these differences in corruption levels between first- and second-term mayors are exclusively determined by experience, then there should be no distinction between visible and nonvisible violations. Second-term mayors should commit more irregularities of both types, as long as these learning technologies are complementary.

*Reelection Incentives and Other Dimensions of Political Performance.*—Up to this point we have shown that mayors refrain from rent extraction when faced with reelection incentives. Underlying this interpretation is the premise that term limits shorten the political horizon of mayors. One potential concern with this mechanism is the fact that second-term mayors can run for other political offices in the future (or even run again for mayor after a one-term hiatus). In this case, second-term mayors would also have incentives to refrain from corruption in the present and behave similar to first-term mayors. Yet despite the fact that second-term mayors can return to office or run for higher office, few actually do. Among the mayors who were in their second term in 2000, only 12 percent were reelected in 2008, and only 9 percent of mayors ran

TABLE 8—REELECTION INCENTIVES AND OTHER FORMS OF BAD GOVERNANCE

Dependent variable	Share of audited items involving mismanagement			Corruption
	Full sample (1)	Second- and first-term mayors later reelected (2)	Second- and first-term mayors who served previously as mayors (3)	Full sample (4)
Mayor in first term	0.054 [0.102]	0.069 [0.151]	0.088 [0.180]	−0.036 [0.013]***
Observations	366	243	218	366

Municipal characteristics	Yes	Yes	Yes	Yes
Political and judicial institutions	Yes	Yes	Yes	Yes
Lottery intercepts	Yes	Yes	Yes	Yes
State intercepts	Yes	Yes	Yes	Yes

Notes: This table reports the effects of reelection incentives on the share of audited items found to involve acts of mismanagement. Column 1 uses the full sample. Column 2 compares the mismanagement levels of second-term mayors to those of the subset of first-term mayors who were reelected in the subsequent mayoral elections. Column 3 includes only municipalities with a second-term mayor and first-term mayors who were mayors in a previous term. Column 4 reports the effects of reelection incentives on corruption for the sample used in estimating the results presented in column 1. Mayor characteristics include the age, gender, education, and party affiliation of the mayor. Municipal characteristics: population expressed in logarithms, percentage of the population that has at least a secondary education, percentage of the population that lives in the urban sector, new municipality, log GDP per capita in 2002, Gini coefficient. Political and judicial institutions include: effective number of political parties in the legislature, the number of legislators divided by the number of voters, the share of the legislature that is of the same party as the mayor, whether the municipality is judiciary district, and the amount of resources sent to the municipality expressed in logarithms. Robust standard errors are displayed in brackets.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

\*Significant at the 10 percent level.

for higher office in 2006. Thus, assuming that politicians expect low probabilities of returning to office and discount future gains, it is reasonable to expect that, on average, second-term mayors will act as if they face real term limits.

Moreover, if mayors respond to reelection opportunities, they will not only refrain from rent extraction, but will also exert effort along other dimensions of political performance. In this subsection, we examine if reelection incentives affect whether mayors procure matching grants from the central government, which is the only mechanism mayors have to attract additional discretionary resources to their municipalities. If the political horizon of second-term mayors is similar to that of first-term mayors, then we would not expect a difference between first- and second-term mayors in the amount of grants they attract.

To test this, we collect annual data on every matching grant solicited by a municipality and the value transferred from the federal government during the 2001–2004 period.<sup>27</sup> These data on matching grants are useful for two reasons. First, unlike other transfers received by the municipality, the receipt of these funds is not formula based, but depends on the ability and effort of the mayor to procure them. Second,

<sup>27</sup> Matching grants are contracts between the federal government and the municipality specifying each party's contribution to the construction of public works. However, in virtually all cases, municipalities contribute less than 10 percent of the expected costs.

in almost all cases, these contracts designate the construction of some large public works projects, such as road construction, schools, health clinics, and rural electrification, among others. Thus, they constitute highly visible projects that can garner electoral support. For these reasons, we would expect that, on average, mayors with reelection incentives procure more grants than those who do not face reelection incentives.

To test the effects of reelection incentives on the receipt of matching grants, we exploit the panel structure of the data to estimate the following model:

$$(3) \quad y_{it} = \alpha_0 + \sum_t \alpha_t (T_t \times I_i) + \lambda_t + \eta_i + \epsilon_{it},$$

where  $y_{it}$  denotes one of three dependent variables: (i) an indicator for whether the municipality signed a matching grant in year  $t$ ; (ii) the log value of all contracts signed in year  $t$  expressed in per capita terms; and (iii) the percentage of signed contracts disbursed in year  $t$ .<sup>28</sup> The term  $T_t \times I_i$  denotes the interaction between being a first-term mayor  $I_i$  and the year of the contract;  $\lambda_t$  denotes year effects; and  $\eta_i$  represents municipal fixed-effects. The error term,  $\epsilon_{it}$ , is clustered at the municipality level.

Table 9 presents regression results from estimating variants to equation (3). In odd columns, we estimate the model without municipal fixed-effects (and thus included a dummy for whether the mayor is in his first term) but control for various municipal and mayor characteristics. In column 2 and 4 we include municipal fixed-effects and differential time trends by each of our municipal and mayor characteristics. The coefficients presented in columns 1 and 2 reveal a striking pattern of whether or not a municipality received a contract. During their first year in office, first-term mayors are 5.8 percentage points less likely than second-term mayors to attract any grants. This result is not too surprising given their lack of experience. But in subsequent years, first-term mayors become more likely to procure grants. For instance, during the electoral year 2004, first-term mayors were 14 percentage points more likely to attract a grant than second-term mayors (robust standard error = 0.049). Moreover, the difference between first- and second-term mayors increases as the elections approach. Although we cannot reject that these coefficients are not statistically the same, the economic differences in magnitudes are quite meaningful.

We also observe a similar pattern in columns 3 and 4, when we use the per capita value of the contract as the dependent variable. Again, while first-term mayors attract significantly fewer funds during their first year in office, the difference is quickly reversed in subsequent years. Given that the average length of a matching grant is 17 months, the electoral rewards for procuring them can be high even in the second year of office.

Finally, in the remaining columns of Table 9 we examine whether the percentage of funds disbursed exhibits a similar pattern. Mayors who face the possibility of reelection have an incentive not only to attract more grants, but also to sign contracts in which the funds can be disbursed prior to the elections, so as to claim credit for

<sup>28</sup>To avoid problems associated with  $\ln(0)$ , we add a 1 to the contract value before taking the log.

TABLE 9—REELECTION INCENTIVES AND MATCHING GRANTS

Municipal and mayor characteristic $\times$ time trends	N	Y	N	Y	N	Y

Notes: This table reports the effects of reelection incentives on the procurement of matching grants. The specification presented in the odd columns includes municipal and mayor characteristics and year intercepts, whereas the specifications in the even columns also include municipality fixed-effects and linear time trends interacted with our mayor and municipal covariates. The sample represents yearly data from 2001 to 2004 for each municipality in our sample. Robust standard errors clustered at the municipality level are displayed in brackets.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

\*Significant at the 10 percent level.

the public work. In columns 5 and 6, we find that first-term mayors receive a much higher percentage of the signed contract compared to second-term mayors. Again, this difference increases as the elections near.

Overall the results presented in Table 9 are consistent with our findings that electoral accountability reduces corruption practices. Moreover, the findings are difficult to reconcile with an alternative model in which experience drives the differences in political performance between first- and second-term mayors. If experience were the principal mechanism, we would find a pattern where either second-term mayor consistently attracted more grants over time, or where the difference in grants attracted by first- and second-term mayors decreased over time.

#### F. Local Context and Reelection Incentives

In this section we explore the extent to which the effects of reelection incentives on corruption might vary according to local characteristics that affect electoral accountability. In order to shed light on the empirical results, we start by discussing some natural extensions to the simple model presented in Section I.

The asymmetry of information between voters and politicians lies at the heart of political agency models. Hence, factors that influence access to information may affect how reelection incentives affect corruption. To see this in the framework

proposed in Section I, suppose that with some probability,  $\tau$ , voters observe their politician's type after he has chosen his action,  $e$ , and before the election is held. In this case, the likelihood that a corrupt politician will pool with noncorrupt politicians will depend negatively on  $\tau$ , (i.e.,  $\partial\lambda/\partial\tau$ , where  $\lambda = G((1 - \tau)\delta(\mu + E))$ ). Thus, as the likelihood that a corrupt politician is detected in the first period increases (i.e., voters have more information), a corrupt politician will be less likely to pool with noncorrupt politicians, and hence discipline will be reduced. But as corrupt politicians become less disciplined, they are less likely to survive into a second period and the quality of the average politician who survives into a second mandate improves. Hence, the overall effect of an increase of information that allows voters to identify a politician's type is ambiguous: corruption will decrease in the second period and potentially increase in the first because those corrupt mayors will now extract as much rent as they can in the first period.<sup>29</sup> Empirically, with a cross section of mayors, one would expect the difference in corruption between first- and second-term mayors to be smaller in municipalities where there is more access to information that allows voters to uncover the politician's type.

To proxy for access to information, we use an indicator for the presence of local media in the form of either a radio station or a local newspaper. Since the redemocratization of Brazil in the early 1980s, local radio has played a central role in local politics, and has been a natural medium for informing voters about politician behavior (Ferraz and Finan 2008). Because we want our proxy to identify places with better access to information, we also include in our definition of media the existence of local newspapers. Although circulation rates of Brazilian newspapers tend to be relatively low, newspapers may offer a greater degree of investigative journalism than radio stations.<sup>30</sup>

An additional source of heterogeneity stems from differences across municipalities in the potential punishment of engaging in corruption. For instance, the probability of being prosecuted and punished for corruption charges is likely to be higher in municipalities where the judiciary has a public prosecutor, thus increasing the cost of engaging in corrupt activities. To capture this feature in our framework, one could assume that corrupt mayors receive a private benefit  $\theta r_t$ , where  $\theta \leq 1$  represents the cost of being corrupt. Corrupt mayors, in deciding to accept the private benefit, trade off the rents in the first period  $r_1$  to the prospects of future benefits  $(1/\theta)\delta(\theta\mu + E)$ . Thus, as corruption costs increase, reducing the future benefits of rent extraction, politicians will become less disciplined and the selection effect will increase. Therefore, we would expect that in municipalities where the costs of engaging in corruption are higher, the difference in corruption between first- and second-term mayors would also be lower. To distinguish between municipalities where the cost of engaging in corruption may be higher, we use an indicator for the presence of a judge, which can increase the likelihood of being prosecuted.<sup>31</sup>

<sup>29</sup> Alternatively, one could assume that rather than observe the politician's type, we could suppose that actions are observed only with some probability  $\tau$ . The probability of a politician acting disciplined is then:  $\lambda = G(\tau\delta(\mu + E))$ . In this situation, increasing the probability of observing the politician's action increases the probability that bad types pool with good types. Thus, in this model, we would expect the difference in corruption levels between first- and second-term mayors to be higher in areas with local media.

<sup>30</sup> Our results are similar if we use only the presences of a local radio station as our proxy for access to information.

<sup>31</sup> In Brazil, the presence of a judge depends on whether the municipality is a judiciary district (*comarca*), which in turn depends on local characteristics such as population, local revenues, and the number of judiciary processes.

Political competition may also determine how reelection incentives affect corruption. An increase in electoral advantage will reduce the disciplining effect, as the probability of being reelected increases, even if the corrupt mayor does not pretend to be noncorrupt. Thus, the difference between first- and second-term mayors is smaller in municipalities where the elections are less competitive.

Finally, a mayor's political support might affect corruption choices. If the mayor has a majority in the local legislature, he will be able to pass legislation, increase public employment, and adopt other strategies that increase his reelection chances. Everything else constant, he can be less disciplined and still get reelected to a second term. Thus, we expect the difference in corruption between first- and second-term mayors to decrease as the support in the local legislature increases.

In Table 10, we see that the presence of public prosecutors or local media reduces the corruption differential between first-term and second-term mayors. Among municipalities with public prosecutors, there is only a small difference in corruption levels between first- and second-term mayors (column 1), and in municipalities with local media the difference is only 1.4 percentage points (column 2). In contrast, among municipalities where there does not exist any local media, second-term mayors are almost 10 percentage points (robust standard error = 0.03) more corrupt than first-term mayors, which represents an average R\$525,000.

We also find that the presence of local media has a direct effect on corruption levels (column 2). In municipalities with a second-term mayor, the existence of media reduces corruption by 5.3 percentage points. But in municipalities with a first-term mayor, corruption is 3.3 percentage points higher in areas with media relative to those without. This is again consistent with the theory. Because media presence increases the probability that the politician's type is revealed, we expect less discipline among first-term mayors (and thus higher corruption levels) but less corruption in municipalities with second-term mayors due to the positive selection effects. The direct effects of having a local prosecutor are similar to those of media, but are not statistically significant.

Columns 3 and 4 report how the second-term effect varies with the degree of political competition, as measured by the proportion of the local council that is from the same party as the mayor (column 3) and by a political Herfindahl index in the previous election (column 4).<sup>32</sup> As reported in column 3, political competition increases the difference in corruption levels between first- and second-term mayors. When only 9 percent of the legislative council is from the same political party as the mayor (fifth percentile of the distribution), there is an 8.8 percentage point difference between first- and second-term mayors. However, when the political support of the incumbent mayor represents 55 percent of the legislative branch, there is no difference in corruption levels between first- and second-term mayors. The results reported in column 4 tell a similar story. For instance, among municipalities where the Herfindahl index is 0.08 (the first percentile of the distribution), first-term mayors are 3.9 percentage points less corrupt than second-term mayors. In contrast, when elections are less competitive at 0.528 (the 99th percentile of the distribution), the difference in corruption levels between first- and second-term mayors is -0.007. In

<sup>32</sup>The Herfindahl index is computed by dividing one by the effective number of political parties.

TABLE 10—LOCAL CHARACTERISTICS AND THE EFFECT OF REELECTION INCENTIVES ON CORRUPTION

Dependent variable	Share of audited resources involving corruption			
	(1)	(2)	(3)	(4)

P-value	0.02	0.00	0.02	0.04
Observations	476	476	476	476
R <sup>2</sup>	0.21	0.23	0.21	0.21
Mayor characteristics	Yes	Yes	Yes	Yes
Municipal characteristics	Yes	Yes	Yes	Yes
Political and judicial institutions	Yes	Yes	Yes	Yes
Lottery intercepts	Yes	Yes	Yes	Yes
State intercepts	Yes	Yes	Yes	Yes

Notes: This table reports the effects of reelection incentives on share of resources involving corruption. The sample includes all 476 municipalities. All regressions include mayor characteristics, municipal characteristics, political and judiciary characteristics, and state and lottery intercepts. Political competition is defined as 1 divided by the effective number of political parties. Media is defined as an indicator for whether the municipality has a local AM radio station or newspaper. Mayor characteristics include the age, gender, education, and party affiliation of the mayor. Municipal characteristics: population expressed in logarithms, percentage of the population that has at least a secondary education, percentage of the population that lives in the urban sector, new municipality, log GDP per capita 2002, Gini coefficient. Political and judicial institutions include: effective number of political parties in the legislature, the number of legislators divided by the number of voters, the share of the legislature that is of the same party as the mayor, whether the municipality is judiciary district, and the amount of resources sent to the municipality expressed in logarithms. Robust standard errors are displayed in brackets.

\*\*\*Significant at the 1 percent level.  
\*\*Significant at the 5 percent level.  
\*Significant at the 10 percent level.

effect, the results presented in columns 3 and 4 suggest that municipalities characterized by low competition exhibit no differential effect in rent extraction between first- and second-term mayors. First-term mayors with an extreme electoral advantage can afford to be as corrupt as a lame-duck mayor since his reelection is practically guaranteed.

In sum, the effects reported in Table 10 are consistent with a model where incumbent politicians are responsive to reelection incentives. These interaction effects also provide even further evidence that a model of experience cannot be the principal mechanism explaining the difference in corruption levels between first- and

second-term mayors. For instance, in a simple learning model, we would not observe first-term mayors behaving as second-term mayors in municipalities where the political competition is low.

## VI. Testing for Alternative Explanations

Our analysis shows that mayors who can be held accountable at the polls will engage in less corruption. First-term mayors steal 27 percent fewer resources than second-term mayors, even when accounting for potential biases in political ability and experience.

An obvious concern in interpreting this finding is that it may simply reflect corruption on the part of the auditors. Because first-term mayors have more incentive to bribe the auditors for a more favorable report, we could be capturing the effects of reelection incentives on bribing rather than the effects of career concerns on actual corruption. While it is difficult to test this hypothesis directly, we provide suggestive evidence that this is not the case. For instance, if first-term mayors are more likely to bribe auditors, we might expect those who were audited during the election year or affiliated with either the federal government or state government to receive more favorable reports.

We explore these possibilities in Table 11. In columns 1–3 we regress our measure of corruption on the first-term indicator and interaction terms with variables that would suggest larger incentives for bribing the auditors. In column 1 we test for differential auditing according to whether the municipality was drawn to be audited during the 2004 election year. We show there is no difference in corruption levels between first- and second-term mayors depending on whether they were audited during the electoral year or not (coefficient = 0.001, robust standard error = 0.017). We also do not find any differential effects by whether the mayor belongs to the same party of the president—the PT (Worker’s Party) (column 2) or the state governor (column 3).<sup>33</sup> Another way auditors may have favored first-term mayors is to audit less valued projects. Although this is unlikely in explaining the patterns that we find in the main regressions, we regress the log value of projects audited on an indicator for whether the mayor is in a first term. As reported in column 4, we again do not find any statistically significant difference in the amount of resources audited between first- and second term-mayors. We also do not find any differential effects depending on whether the municipality was audited during the 2004 electoral year (column 5), whether the mayor was from the Worker’s Party (column 6), or whether the mayor was from the same party as the governor (column 7).

In addition to the previous analysis, there are several reasons why it is unlikely that differences in corruption between first- and second-term mayors reflect corrupt auditors. First, they are federal public employees hired based on a highly competitive public examination and high salary. Moreover, each team of auditors reports to a regional supervisor. Therefore, it is hard to cheat individually, and the cost of getting

<sup>33</sup>Ferraz and Finan (2008) compare corruption levels using the count measure between first-term mayors that were audited before the election versus after the election. They do not find any evidence that corruption levels differed between these two groups along various dimensions.

TABLE 11—TESTING FOR THE POLITICAL MANIPULATION OF AUDIT REPORTS

Dependent variable	Share of audited resources indicated as corruption			Log(value projects audited)

caught is high. According to program officials, there has never been an incidence in which auditors have even been caught receiving bribes.

Another explanation for the difference in reported corruption levels is that lame duck mayors, who are no longer accountable to voters, simply have less incentive to hide or are less careful in their attempt to hide corruption. Although this hypothesis is in many respects observationally equivalent to what we find, it is unlikely that this could explain the estimated effects, since this program was unexpected and the audits were based on past behavior. Moreover, although second-term mayors may not face electoral retribution, they have an incentive to hide corruption due to potential judiciary prosecution.

## VII. Conclusions

The abuse of entrusted power by democratically elected politicians through rent seeking and corruption is a central issue in a large number of countries. Thus, the capacity of elections to solve the inherent agency problem between voters and

elected representatives has been a central area of research in political economy. In this paper, we examine whether electoral accountability induced by the possibility of reelection can discipline incumbent politicians and control their rent-seeking behavior. We provide empirical evidence that reelection incentives reduce corruption. Using a new dataset of corruption practices by local politicians in Brazil, and exploiting the variation in electoral incentives provided by term limits, we show that first-term mayors eligible for reelection are associated with significantly less corruption than second-term mayors who face a binding term limit. This difference in corruption is remarkably robust to various specifications and alternative interpretations, such as unobserved differences in municipal characteristics, political ability, or experience between first- and second-term mayors. These findings suggest that electoral rules that enhance political accountability play a crucial role in constraining politicians, even in an institutional context where corruption is pervasive and elites dominate local politics.

We interpret our findings in the context of a simple political agency model where incumbent mayors with electoral concerns restrain from corruption due to the possibility that voters learn about their rent-seeking behavior and punish them at the polls. Consistent with this mechanism, we find that the effect of electoral accountability on reducing corruption is higher in places where the probability of corrupt practices being detected is higher (as measured by the presence of local media and local judiciary agents). Moreover, while politicians with reelection incentives should refrain from rent-seeking activities that voters can observe, they need not refrain from committing irregularities that voters either cannot detect or care less about. We find that violations that are unlikely to be uncovered by voters do not differ between first- and second-term mayors.

The result that electoral accountability can reduce corruption also raises the critical question of how to make local governments more accountable. Allowing citizens to have better information about policy implementations and corruption practices is one possibility. In this regard, audit policies that reveal new information about government quality can increase the probability that bad politicians get caught. Together with the use of "information campaigns," it can help voters select better leaders. Finally, political competition and the overall improvement of the quality of politicians, especially in local legislatures, can enhance checks and balances between executive and legislative powers.

Finally, given our findings, it is natural to ask whether a system of two-term limits is optimal to reduce the incentives for rent extraction. Although Michael Smart and Sturm (2006) provide theoretical justification for why a two-term limit regime might be optimal under some conditions, we are unfortunately unable to test this. Unlike the variation that exists in term-limits across the United States, our research design can identify only the effects of reelection incentives on corruption under a two-term regime relative to a one-term regime. We cannot estimate, for instance, how politicians would behave if they were elected for a third term, or even reelected indefinitely. Moreover, the fact that incumbent politicians respond to electoral incentives and reduce corrupt practices does not imply that term limits should necessarily be abolished. In theory, term limits can have beneficial effects as well. Because reelection incentives can induce politicians to pander to voters or adopt inefficient policies near elections, term limits may provide politicians with the

freedom to enact policies that are more socially optimal (Brandice Canes-Wrone, Michael C. Herron, and Kenneth W. Shotts 2001). Without term limits, entrenchment effects also become a concern. Although we suspect that this is less likely to occur in Brazil where incumbency rates are low, entrenchment effects can deter the entry of new leaders and reduce the overall quality of the political class in the long run (Andrew R. Dick and John R. Lott Jr. 1993; James M. Buchanan and Roger D. Congleton 1994). In sum, despite the fact that reelection incentives constrain corruption, further research is needed to assess whether electoral accountability affects other aspects of governance and ultimately improves voter welfare.

#### APPENDIX A: CODING THE AUDIT REPORTS

This Appendix explains how we used the audit reports to construct indicators of corruption. We provide the definition used for each type of irregularity and include an illustrative example drawn from the reports.<sup>34</sup>

##### *Examples of Political Corruption*

**Health-related purchases without procurement using false receipts:** The ministry of Health transferred to the municipality R\$321,700 for the *Programa de Atenção Básica*. The municipal government used fake receipts valued at R\$166,000 to provide proof of purchase. Furthermore, there is no proof that the goods were purchased since there were no registered entries of the merchandise in the stock. Also, in 2003 the municipality bought medicine valued at R\$253,300 without procurement. In 2004, the value was R\$113,700, also without procurement. We classified this violation as an incidence of irregular procurement and diversion of public funds in the area of health. We valued this irregularity as a diversion of R\$166,000. This irregularity occurred in Capelinha, Minas Gerais, which was selected for audit by the 9th lottery.

**Evidence of irregularities in well construction:** The Ministry of National Integration transferred R\$117,037 to the municipality for the maintenance of water infrastructure. The working plan specified the maintenance of ten wells and four dams. None of these repairs was made. Instead, the dam Henrique Dantas, located on a private farm, was repaired. We classified this violation as an incidence of diversion of public funds in the area of water and sanitation. We valued this irregularity as a diversion of R\$117,037. This irregularity occurred in Santa Cruz, Rio Grande do Norte, which was selected for audit by the 9th lottery.

**Overinvoicing of more than R\$3 million in road construction:** The firm Mazda was hired, without procurement, to build approximately nine kilometers of a road. The cost of the construction was estimated at R\$1 million based on similar construction. The receipts presented by Mazda and paid by the government totalled R\$5 million. No further documentation was shown by the municipal government proving the need for the additional amount of resources. The auditors found that Mazda did not have any

<sup>34</sup>For access to the summary of the audit reports, see [www.cgu.gov.br](http://www.cgu.gov.br).

experience with construction and had subcontracted the firm CTE for R\$1.8 million to do the construction. Hence, the project was overpaid by more than R\$3 million. As evidence of corruption, it was later found that Mazda gave an apartment to the mayor and his family valued at R\$600,000, suggesting a kickback. We classified this violation as an incidence of overinvoicing in the area of infrastructure. We valued this irregularity as a diversion of R\$3.2 million. This irregularity occurred in São Francisco do Conde, Bahia, which was selected for audit by the 6th lottery.

## APPENDIX B: DATA SOURCES

The data used in the paper come from a variety of sources. The data are at the level of the municipality, the lowest government unit below a state in Brazil.

**Municipal demographic characteristics:** The 2000 population census provides socioeconomic and demographic characteristics of municipalities. The variables we include in our analysis are: population size, percentage of urban households, Gini coefficient, and the percentage of adults with secondary education. In addition, we include the level of income measured by municipal GDP per capita estimated by the IBGE. These variables are important determinants of corruption, as shown by Edward L. Glaeser and Raven E. Saks (2006) and Daniel Treisman (2000).

**Municipal institutional and public management characteristics:** Our second complementary data source from IBGE is a municipality survey, *Perfil dos Municípios Brasileiros: Gestão Pública*, conducted in 1999 and 2001. The survey provides structural features of the municipality such as the existence of local daily newspaper, radio, local public prosecutors, and the age of the municipality. These data also characterize various aspects of the public administration, including the existence of laws that govern its budgetary and planning procedures.

**Election data:** Results from the 2000 and 2004 mayoral elections are available from the *Tribunal Superior Eleitoral* (TSE). These data contain vote totals for each candidate by municipality, along with various individual characteristics such as the candidate's gender, education, occupation, and party affiliation. We use this information to construct measures of electoral performance, and to control for individual mayor characteristics that might affect corruption. We also use the TSE data to build measures of a mayor's political support in the local legislature as well as the size of the legislature.

**Public finance data:** We use public finance data, *FINBRA*, from the *Tesouro Nacional* to construct a measure of intergovernmental transfers received by municipalities. These data control for potential differences in the amount of resources received from the state and federal governments across municipalities.

**Matching grants data:** We use data on matching grants solicited from the federal government by the municipality. These transfers are for the implementation of a program, project, or activity for which there is common interest from both the municipal and federal governments. Most transfers are related to public service provision (e.g., improve education quality, health quality, and urban infrastructure).

Information on each project, including the amount of resources transferred and the initial and final dates, is available at: [www.portaltransparencia.gov.br](http://www.portaltransparencia.gov.br).
